# COMP 2211 Exploring Artificial Intelligence

## Artificial Neural Network - Multilayer Perceptron

Dr. Desmond Tsoi

Department of Computer Science & Engineering
The Hong Kong University of Science and Technology, Hong Kong SAR, China

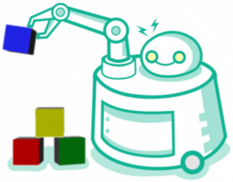
# Perceptron

- Recall the perceptron is a simple biological neuron model in an artificial neural network.
- It has a couple of limitations:
  1. Can only represent a limited set of functions.
  2. Can only distinguish (by the value of its output) the sets of inputs that are linearly separable in the inputs.
     - One of the simplest examples of non-separable sets is logical function XOR

**How to remedy these limitations?**

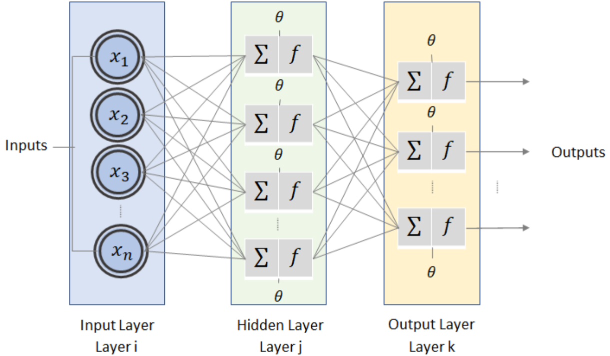
The output of one perceptron can be connected to the input of other perceptron(s). This makes it possible to extend the computational possibilities of a single perceptron.

$\Rightarrow$ Multi-layer Perception



# Multi-Layer Perceptron Neural Network

- Multi-layer perceptron (MLP) neural network is a type of feed-forward neural network. (Feed-forward here means nodes in this network do not form a cycle.)
- It consists of three types of layers:
  - Input layer (also called layer i)
  - Hidden layer (also called layer j)
  - Output layer (also called layer k)



- $x_1, x_2, \ldots, x_n$ are the inputs
- $\sum$ is summation
- $w_{ab}$ is the weight connecting node a to node b
- $f$ is an activation function
- $\theta$ is a bias

# Questions

- How to initialize the weights and biases?
  Answer: Initialize them to some small random values.
- How to perform training?
  Answer:
  1. Let the network calculate the output with the given inputs (forward propagation)
  2. Calculate the error (i.e. the difference between the calculated outputs and the target outputs)
  3. Update the weights and biases between the hidden and output layer (backward propagation)
  4. Update the weights and biases between the input and hidden layer (backward propagation)
  5. Go back to step 1
- When to stop training?
  Answer:
  - After a fixed number of iterations through the loop.
  - Once the training error falls below some threshold.
  - Stop at a minimum of the error on the validation set.

Training can be very slow in networks with multiple hidden layers!

# How to update the weights and biases?

- The formula for updating weights and biases are derived by minimizing the error:

$$E = \frac{1}{2} \sum_{all\ k} (O_k - T_k)^2$$

using gradient descent.

$$\delta_k = (O_k - T_k) O_k (1 - O_k)$$
$$\delta_j = O_j (1 - O_j) \sum_{k \in K} \delta_k w_{jk}$$

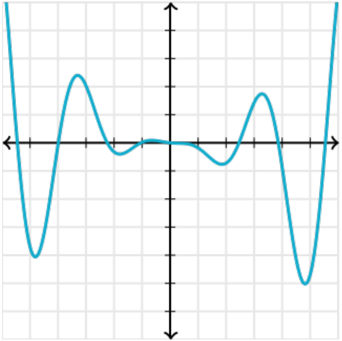
$$w_{jk} \leftarrow w_{jk} - \eta \delta_k O_j$$
$$w_{ij} \leftarrow w_{ij} - \eta \delta_j O_i$$
$$\theta_j \leftarrow \theta_j - \eta \delta_j$$
$$\theta_k \leftarrow \theta_k - \eta \delta_k$$

where $O_k$ is the computed output of node in layer k, $T_k$ is the target output of node in layer k, $\eta$ is the learning rate.

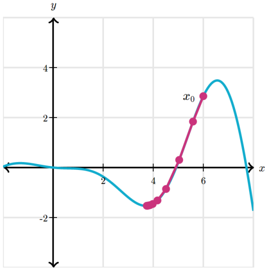
# Intuitive Idea of Gradient Descent

Consider the function

$$f(x) = \frac{x^2 cos(x) - x}{10}$$



- As we can see from the left, this function has many local minima.
- If we choose $x_0 = 6$ and $\eta = 0.2$, for example, gradient descent moves as shown in the graph below.

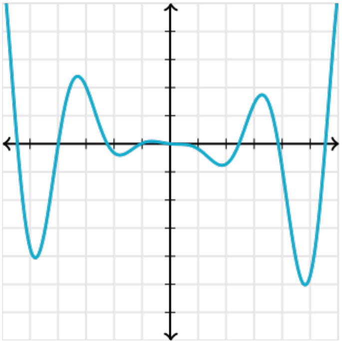


- The first point is $x_0$, and lines connect each point to the next one in the sequence. After only 10 steps, we converged to the minimum near x=4.

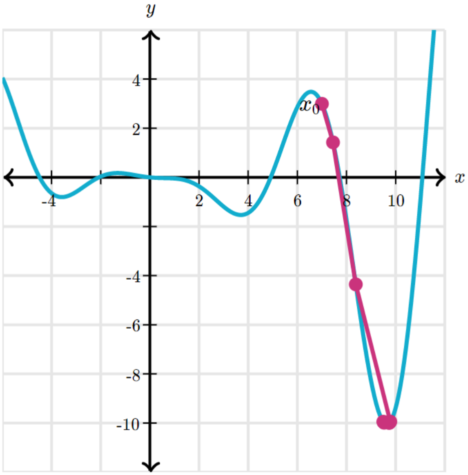
# Intuitive Idea of Gradient Descent (Cont'd)

Consider the function

$$f(x) = \frac{x^2 cos(x) - x}{10}$$



- If we start at $x_0 = 7$ with $\eta = 0.2$, we descend into a completely different local minimum.



# Intuitive Idea of Gradient Descent (Cont'd)

- To minimize the function $E = \frac{1}{2}\sum_{all\ k}(O_k - T_k)^2$, we can follow the negative of the gradient (slope in 2D), and thus go in the direction of steepest descent. This is gradient descent.
- Formally, if we start at a point $x_0$ ($x_0$ can be a weight or a bias) and move a positive distance $\eta$ in the direction of the negative gradient, then our new and improved $x_1$ ($x_1$ can be a weight or a bias) will look like this:

$$x_1 = x_0 - \eta \nabla f(x_0)$$

- More generally, we can write a formula for tuning $x_n$ ($x_n$ can be a weight or a bias) into $x_{n+1}$ ($x_{n+1}$ can be a weight or a bias):

$$x_{n+1} = x_n - \eta \nabla f(x_n)$$

- Starting from an initial guess $x_0$ ($x_0$ can be a weight or a bias), we keep improving little by little until we find a local minimum.
- This process may take thousands of iterations, so we typically implement gradient descent with a computer.

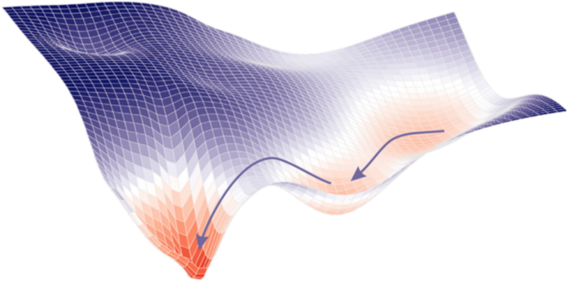
# Gradient Descent

**Question**

Why is gradient descent used rather than directly to find a closed-form mathematics solution?

Answers:

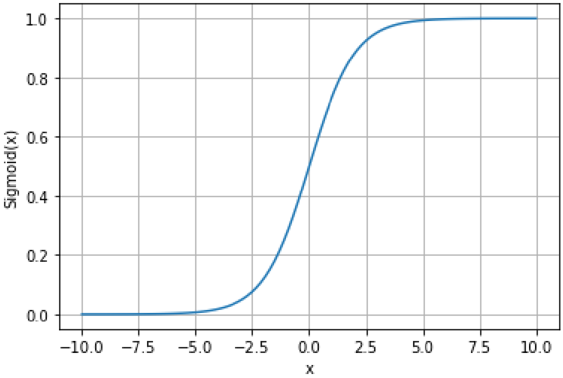
- For most non-linear regression problems, there is no closed-form solution.
- Even for those with a closed-form solution, gradient descent is computationally cheaper (faster) to find the solution.



# Activation Function Again

- For multi-layer perceptron, the Sigmoid function is used as an activation function for neurons since it is continuous and differentiable (i.e. can be used to find the weights updating rules easily).

$$\sigma(x) = \frac{1}{1 + e^{-x}}$$



# Learning Steps

1. Run the network forward with your input data to get the network output.
2. For each output node, compute

$$\delta_k = (O_k - T_k) O_k (1 - O_k)$$

3. For each hidden node, compute

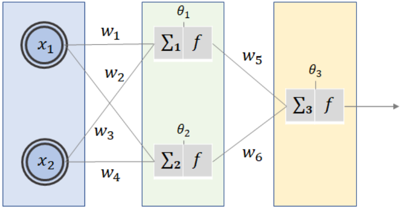
$$\delta_j = O_j (1 - O_j) \sum_{k \in K} \delta_k w_{jk}$$

4. Update the weights and biases as follows:

$$\begin{aligned} w_{jk} &\leftarrow w_{jk} - \eta \delta_k O_j \\ w_{ij} &\leftarrow w_{ij} - \eta \delta_j O_i \\ \theta_j &\leftarrow \theta_j - \eta \delta_j \\ \theta_k &\leftarrow \theta_k - \eta \delta_k \end{aligned}$$

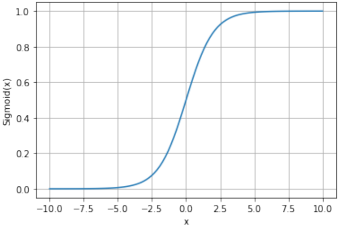
where $\eta$ denotes the learning rate, typically, $\eta$ is a value between 0 and 1.

# Multi-Layer Perceptron Neural Network Example



- Suppose that we will work on a problem of XOR logical operation. The truth table of logical XOR is as follows.

| $x_1$ | $x_2$ | T |
|---|---|---|
| 0 | 0 | 0 |
| 0 | 1 | 1 |
| 1 | 0 | 1 |
| 1 | 1 | 0 |



- Assume the weights are randomly generated, say $w_1 = -0.65$, $w_2 = 0.64$, $w_3 = 1.11$, $w_4 = 0.84$, $w_5 = 0.86$, and $w_6 = -1.38$. Also, assume the biases are randomly generated, say $\theta_1 = 0$, $\theta_2 = 0$, amd $\theta_3 = 0$. Finally, assume $\eta = 0.5$.
- Activation function is $f(x) = \frac{1}{1+e^{-x}}$

# MLP Neural Network Example - Round 1 - Step 1, Forward Propagation

$\eta = 0.5$

- Inputs: $x_1 = 0$, $x_2 = 0$
- Actual Output: $T = 0$
- Weights: $w_1 = -0.65$, $w_2 = 0.64$, $w_3 = 1.11$, $w_4 = 0.84$, $w_5 = 0.86$, and $w_6 = -1.38$
- Bias: $\theta_1 = 0$, $\theta_2 = 0$, $\theta_3 = 0$
- Calculations:
  - $\sum_1 = x_1 \cdot w_1 + x_2 \cdot w_2 = 0 \cdot (-0.65) + 0 \cdot (0.64) = 0$
    Output ($O_{j1}$): $f(\sum_1 + \theta_1) = \text{f}(0+0) = 0.5$

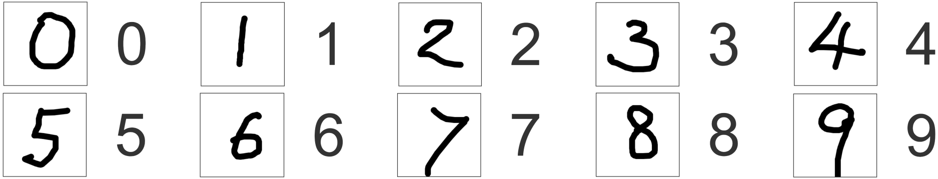
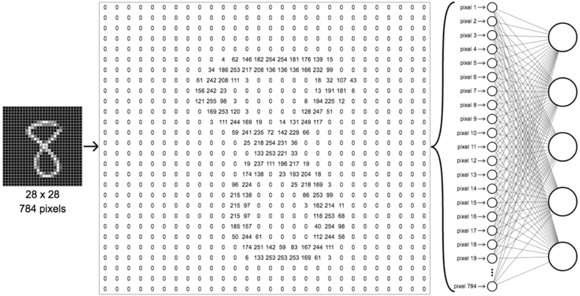
# Handwritten Digits Recognition using MLP

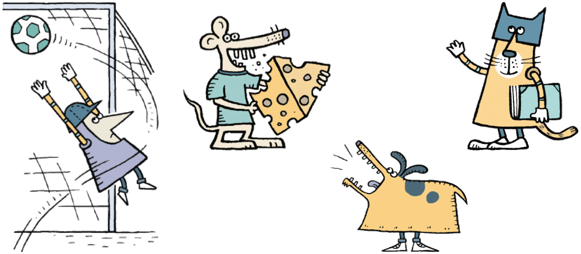
We will build a MLP Artificial Neural Network to recognize/classify handwritten digits.





# Terminologies

- Training data
  - The data our model learn from
- Testing data
  - The data is kept secret from the model until after it has been trained. Testing data is used to evaluate our model.
- Loss function
  - A function used to quantify how accurate a model's predictions were.
- Optimization algorithm
  - It controls exactly how the weights are adjusted during training.



# Dataset

- We use the Modified National Institute of Standards and Technology (MNIST) dataset.
- This dataset contains two sets of samples:
  - Training data: 60000 28 pixel $\times$28 pixel images of handwritten digits from 0 to 9.
  - Testing data: 10000 28 pixel $\times$ 28 pixel images.

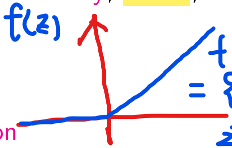
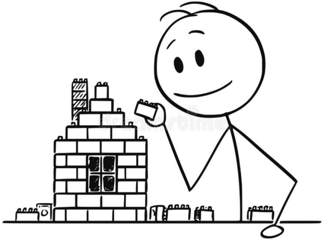
# 4. Build the Model

- Instead of building the model from scratch, we will use the software library, Keras, instead.
- Layers



$f(z) = \begin{cases} 0 & z<0 \\ z & \text{other} \end{cases}$

  - Layer 1: Flatten layer that will flatten 2D image into 1D
  - Layer 2: Input Dense layer with 128 neurons and ReLU activation
  - Layer 3: Hidden Dense layer with 128 neurons and ReLU activation
  - Layer 4: Output Dense layer with 10 Softmax outputs. This layer represents the guess, i.e., the 0th output represents the probability that the input digit is 0, the 1st output represents a probability that the input digit is 1, etc.



Set up MLP.

```
model = Sequential() # Create a Sequential object
```

/value

```
# Input layer
# Add a flatten layer to convert the image data to a single column
model.add(Flatten(input_shape=x_train.shape[1:]))
```

→ make it 1D

X_train (60000, 28, 28)

```
# Hidden layer 1
# Add a dense layer (fully-connected layer) and use ReLU activation function.
# This layer uses L2 loss, computed as l2 * reduce_sum(square(x)), where l2 is 0.002
model.add(Dense(units=128, activation='relu',
                kernel_regularizer=regularizers.l2(0.002)
))
```

← act f.

#neurons

prevent overfitting (diff between predict and expected)$^2$

→ $[0-1]^2$

```
# Hidden layer 2
# Add a dense layer (fully-connected layer) and use ReLU activation function.
# This layer uses L2 loss, computed as l2 * reduce_sum(square(x)), where l2 is 0.002
model.add(Dense(units=128, activation=activations.relu,
                kernel_regularizer=regularizers.l2(0.002)
))
```

= same

```
# Output layer
# Add a dense layer (fully-connected layer) and use softmax activation function.
model.add(Dense(units=10, activation='softmax'))
```

probability.

```
# We apply kernel_regularizer to penalize the weights which are very large causing the
# network to overfit, after applying kernel_regularizer the weights will become smaller.
```

- Print model summary

```
model.summary()
```

\# of weight. $w = 784 \times 128 = 100352 + 128$ bias

neurons.

# 5. Compile the Model

Pred Act

10

1 10

有的是几多

有

```python
# Create an Adam optimizer by creating an object
# Set learning rate to 0.001
# Note: Optimizers are Classes or methods used to change the attributes
# of your machine/deep learning model such as weights and learning rate
# in order to reduce the losses.
adam_optimizer = Adam(learning_rate=0.001)

# Compile the model, i.e., configures the model for training
# Use crossentropy loss function since there are two or more label classes.
# Use adam algorithm (a stochastic gradient descent method)
# Use accuracy as metric, i.e., report on accuracy
model.compile(
    optimizer=adam_optimizer,
    loss=sparse_categorical_crossentropy,
    metrics=['accuracy']
)
```

← how we compile error.

## 6. Train the Model

where the file locate

file name format

```
# TensorBoard is a visualization tool, enabling us to track metrics like
# loss and accuracy, visualize the model graph, view histograms of weights, etc.
# Create TensorBoard object to track experiment metrics like loss and
# accuracy, visualizing the model graph, etc.
log_dir=".logs/fit/" + datetime.datetime.now().strftime("%Y%m%d-%H%M%S")
```

year, month, day + hour min sec.

```
# log_dir: the path of the directory where to save the log files
# histogram_freq: frequency (in epochs) at which to compute activation and weight
# histograms for the layers of the model
tensorboard_callback = TensorBoard(log_dir=log_dir, histogram_freq=1)
```

each epoch

keep intermediate result

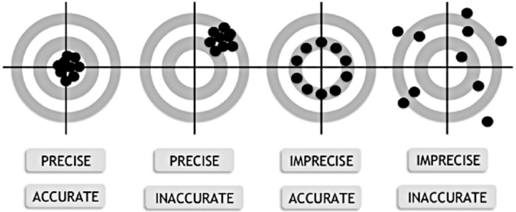
```
# Fit the model, i.e., train the model
# Specify training data and labels, number of epochs to train the model,
# validation data, i.e., data on which to evaluate the loss
# Write TensorBoard logs after every batch of training to monitor our metrices
training_history = model.fit(x_train, y_train, epochs=epochs,
                             validation_data=(x_test, y_test),
                             callbacks=[tensorboard_callback]
)
```

# 7. Evaluate Model Accuracy

```
# Evaluate the model
# Specify testing data and labels
validation_loss, validation_accuracy = model.evaluate(x_test, y_test)
# Print loss and accuracy
print('Validation loss: ', validation_loss)
print('Validation accuracy: ', validation_accuracy)
```

**Output**

```
Validation loss:  0.2004156953573227
Validation accuracy:  0.9646
```



# 8. Save the Model

- Save the entire model to an HDFS (Hadoop Distributed File System) file.
- The .h5 extension of the file indicates that the model should be saved in Keras format as an HDFS file.

```
model_name = 'digits_recognition_mlp.h5'
model.save(model_name, save_format='h5')

loaded_model = load_model(model_name)
```

# 9. Use the Model

- To use the model, we call predict() function

```python
# Use the model to do prediction by specifying the image(s).
# Get back a NumPy array of prediction
predictions = loaded_model.predict([x_test])
print('predictions:', predictions.shape)
```

**Output**

```
predictions: (10000, 10)
```

- Each prediction consists of 10 probabilities (one for each number from 0 to 9). The digit with the highest probability is chosen as that would be a digit that our model is most confident with.

```
# Predictions in form of one-hot vectors (arrays of probabilities).
pd.DataFrame(predictions)
```

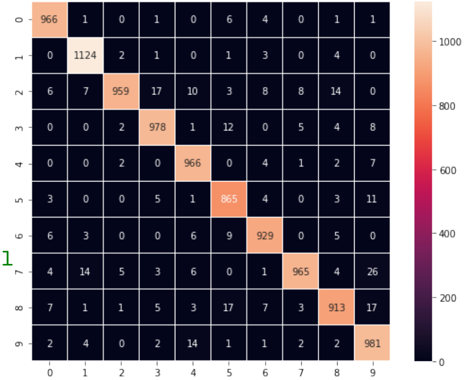
# 10. Plotting a confusion matrix

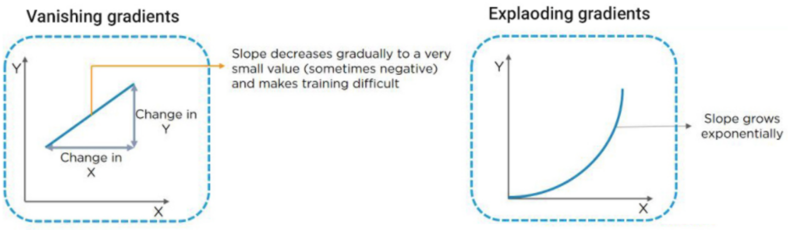
The confusion matrix shows what numbers are recognized well by the model and what numbers the model usually confuses to recognize correctly.

```
# Compute confusion matrix to evaluate the accuracy of a classification
# by creating a confusion_matrix object.
# Specify true labels and prediction results
cm = confusion_matrix(y_test, prediction_results)
# Each image is in size 9x9 inches
f, ax = plt.subplots(figsize=(9, 9))
# Draw heat map to show the magnitude in color
sn.heatmap(
    cm,             # data
    annot=True,     # True (write the data in each cell)
    linewidths=.5, # Width of line that divides each cell
    fmt="d",        # Format of the data, decimal
    square=True,    # Make cell as square-shaped
    ax=ax           # Draw it on ax
)
plt.show()          # Show the figure
```



# Problem: Vanishing Gradient and Exploding Gradient

- One of the problems of training a neural network (especially with many hidden layers) is the vanishing and exploding gradient.
- When we train a neural network, the gradient or the slope can get very big or very small or exponentially small, which makes training difficult.
- As a consequence, the weights are not updated anymore, and learning stalls.

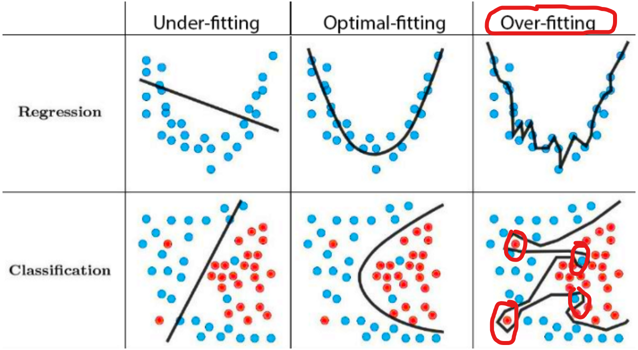


# How to Know Whether Model is Suffering from Vanishing/Exploding Gradient?

- For vanishing gradient
  - The parameters of the higher layers vary dramatically, whereas the parameters of the lower levels do not change significantly for vanishing (or not at all).
  - During training, the model weights may become zero.
  - The model learns slowly, and after a few cycles, the training may become stagnant.
- For exploding gradient
  - The model parameters are growing exponentially.
  - During training, the model weights may become NaN.
  - The model goes through an avalanche learning process.

# Problem: Overfitting and Underfitting

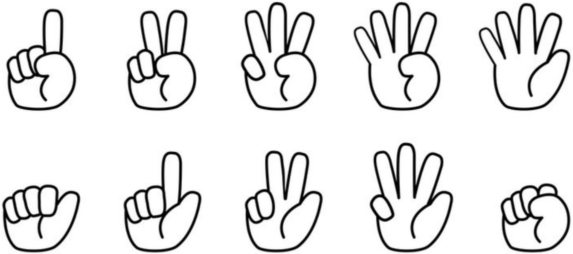
- Overfitting
  - It refers to a model that models the training data too well. It happens when a model learns the detail and noise in the training data to the extent that it negatively impacts the performance of the model on the new data.
- Underfitting
  - It refers to a model that can neither model the training data nor generalize to new data.



L2

# How Many Layers and Number of Neurons in Each of These Layers?

- The input layer
  - Number of layers = 1
  - Number of neurons = Number of features (i.e., columns) in our data (e.g., for XOR, the number of neurons in the input layer is 2)
- The output layer
  - Number of layers = 1
  - Number of neurons = Mostly 1, unless softmax is used (Just like the handwritten digits example)



# How Many Layers and Number of Neurons in Each of These Layers?

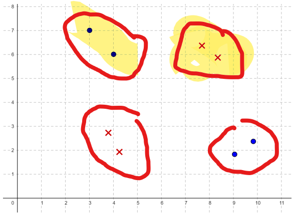
直線分开到

- The hidden layers
  - Number of layers
    - Type 1. If our data is linearly separable, NO hidden layer at all.
    - Type 2. If data is less complex and has few dimensions or features, neural networks with 1 to 2 hidden layers would work.
    - Type 3. If data has large dimensions or features, 3 to 5 hidden layers can be used to get an optimum solution.
  - Number of neurons:
    - * 1. The number of hidden neurons should be between the size of the input layer and the output layer.
    - 2. The most appropriate number of hidden neurons is
      $$\sqrt{\textit{input layer nodes} \times \textit{output layer nodes}}$$
    - 3. The number of hidden neurons should keep decreasing in subsequent layers to get closer to pattern and feature extraction and identify the target class.

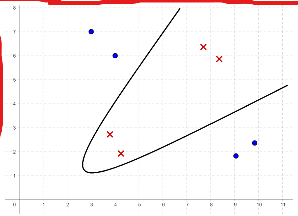
The above algorithms are only a general use case, and they can be moulded according to the use case. Sometimes the number of nodes in hidden layers can also increase in subsequent layers, and the number of hidden layers can also be more than the ideal case. This depends on the use case and problem statement that we are dealing with.

# Example

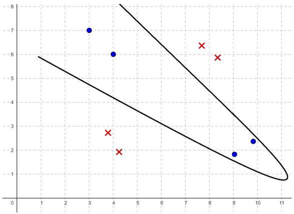
2 Cluster of data. × straight line



Each sample has two inputs and one output presenting the class label

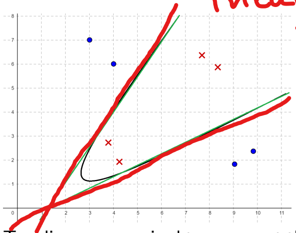


One possible decision boundary separates the data correctly



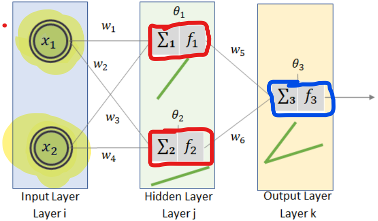
Another possible decision boundary separates the data correctly

1 neuron 1 line => 2 line => 2 neurons.



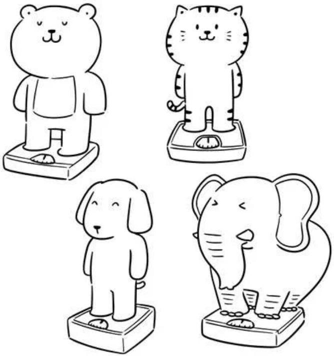
Two lines are required to represent the decision boundary, which tells us the first hidden layer will have two hidden neurons

The two lines are to be connected by another neuron, which is in the output layer



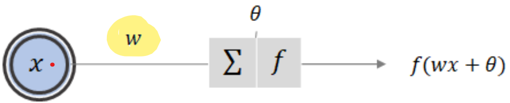
# The Role of Weights

- Weights are the real values associated with each feature which tells the importance of that feature in predicting the final value.



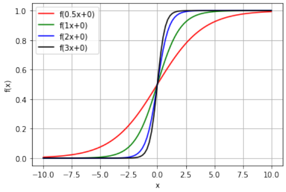
# The Effect for the Change of Weights

- Suppose we have the following perceptron:



- Let's get the output functions by setting $w$ to 1, 2, 3, $\theta$ to 0, and using sigmoid activation function. Now, plot the output functions and figure out the use of weights.

$$y = f(0.5x + 0)$$
$$y = f(1x + 0)$$
$$y = f(2x + 0)$$
$$y = f(3x + 0)$$

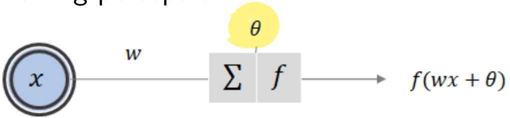


According to the example, we can see that weights control the steepness of the activation function.

# What is the Role of Biases?

θ

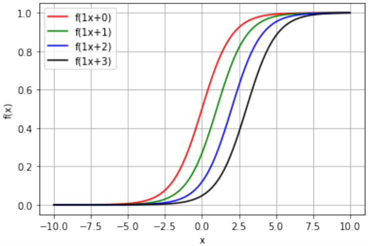
- Suppose we have the following perceptron:



- Now, let's get another set of output functions by setting $w$ to 1, $\theta$ to 0, 1, 2, and 3, and using the sigmoid activation function. Plot the output functions and try to figure out the use of biases.

shift

$$y = f(1x + 0)$$
$$y = f(1x + 1)$$
$$y = f(1x + 2)$$
$$y = f(1x + 3)$$



According to the example, we can see that bias is used for shifting the activation function towards the left or right.

# Activation Functions

super-important

- The choice of activation function in the hidden layer has a large impact on the capability and performance of the neural network.
- An activation function in a neural network defines how the weighted sum of the input is transformed into an output from a node or nodes in a layer of the network.
- All hidden layers typically use the same activation function. The output layer will typically use a different activation function from the hidden layers and is dependent upon the type of prediction required by the model.
- Typically, a differentiable non-linear activation function is used in the hidden layers of a neural network. This allows the model to learn more complex functions.
- Three most commonly used activation functions in hidden layers:
  - Rectified Linear Activation (ReLU)
  - Logistic (Sigmoid)
  - Hyperbolic Tangent (Tanh)

non-linear → for hidden.

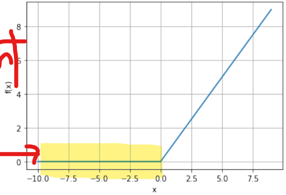
# ReLU Hidden Layer Activation Function

initial $w, \theta \rightarrow$ random

but according to some distribution

- ReLU function is defined as $$f(x) = max(0, x)$$

* avoid vanishing gradient



$f(-ve) = 0$

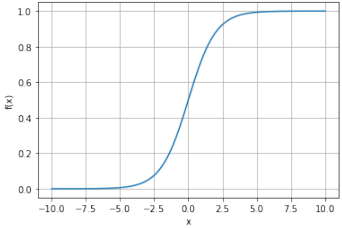
- It is the most common function used for hidden layers.
- It is simple to implement and effectively overcome the limitations of other previously popular activation functions, such as Sigmoid and Tanh. Specifically, it is less susceptible to vanishing gradients.
- When using the ReLU function for hidden layers, it is good to use "He Normal" or "He Uniform" weight initialization and scale input data to the range of 0-1 before training.

```
initializer = tf.keras.initializers.HeNormal()
# initializer = tf.keras.initializers.HeUniform()
layer = tf.keras.layers.Dense(3, kernel_initializer=initializer)
```

initialize w.

# Sigmoid Hidden Layer Activation Function

- Sigmoid function is defined as $$f(x) = \frac{1}{1 + e^{-x}}$$



$f(0) = 0.5$

- The sigmoid activation function is also called the logistic function.
- When using the sigmoid function for hidden layers, it is good to use a "Glorot Normal" or "Glorot Uniform" weight initialization and scale input data to the range 0-1 before training.

  Note: Glorot initializer is also called Xavier initializer.

initialize $W, \theta$

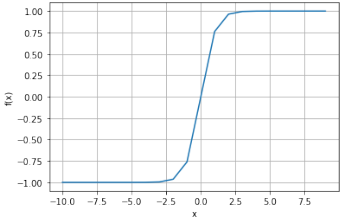
```
initializer = tf.keras.initializers.GlorotNormal()
# initializer = tf.keras.initializers.GlorotUniform()
layer = tf.keras.layers.Dense(3, kernel_initializer=initializer)
```

# Tanh Hidden Layer Activation Function

- Tanh function is defined as

$$f(x) = \frac{e^x - e^{-x}}{e^x + e^{-x}}$$

$f(0) = 0$



- When using the Tanh function for hidden layers, it is good to use a "Glorot Normal" or "Glorot Uniform" weight initialization and scale input data to the range -1 to 1 before training.
  Note: Glorot initializer is also called Xavier initializer.

w. 0

```
initializer = tf.keras.initializers.GlorotNormal()
# initializer = tf.keras.initializers.GlorotUniform()
layer = tf.keras.layers.Dense(3, kernel_initializer=initializer)
```

# How to Choose a Hidden Layer Activation Function?

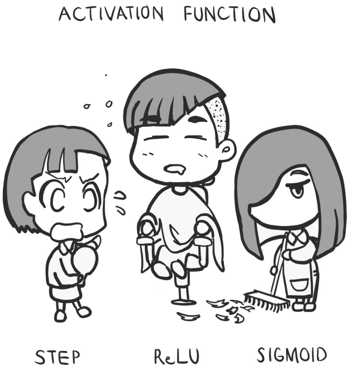
- Both the Sigmoid and Tanh functions can make the model more susceptible to problems during training via the so-called vanishing gradients problem.
- The activation function used in hidden layers is typically chosen based on the type of neural network architecture.
- Modern neural network models with common architectures, such as MLP and CNN (will be mentioned soon), will use the ReLU activation function or extensions.
- Recurrent networks (a type of neural network that has at least one loop) still commonly use Tanh or sigmoid activation functions, or even both.
- Summary

| Neural Network | Commonly Used Activation Function |
|---|---|
| Multi-layer Perceptron (MLP) | ReLU activation function |
| Convolutional Neural Network (CNN) | ReLU activation function |
| Recurrent Neural Network (RNN) | Tanh and/or Sigmoid activation function |

loop.

# Activation Function for Output Layers

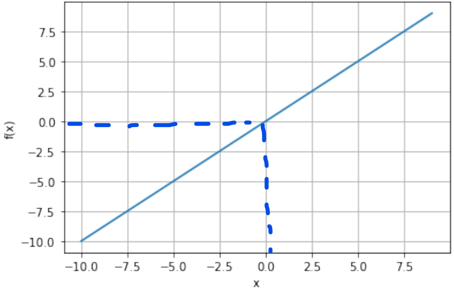
- The output layer is the layer in a neural network model that directly outputs a prediction.
- There are three commonly used activation functions for use in the output layer.
  1. Linear
  2. Logistic (Sigmoid)
  3. Softmax



# Linear Output Activation Function

- The linear output activation function is defined as:

$$f(x) = x$$



- The linear activation function is also called "identity" (multiplied by 1.0) or "no activation".
- Target values used to train a model with a linear activation function in the output layer are typically scaled before modeling using normalization or standardization transforms.

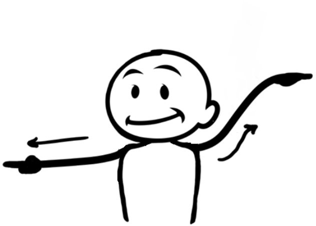
# Sigmoid Output Activation Function

- Recall, the Sigmoid activation function is defined as:

$$f(x) = \frac{1}{1 + e^{-x}}$$

- Target labels used to train a model with a Sigmoid activation function in the output layer will have the values 0 or 1.

$$0 \le f(x) \le 1$$



$$y = \frac{1}{1+e^{-x}}$$

# Softmax Output Activation Function

- Softmax is a mathematical function that converts an array (or vector) of numbers into an array (or vector) of probabilities.
- The softmax function is defined as:

compute new set of value for x.

$$\mathbf{x} = [x_0, x_1, \ldots, x_{n-1}]$$

$$x_0 = \frac{e^{x_0}}{(e^{x_0} + e^{x_1} + \cdots)}$$

$$f(x_i) = \frac{e^{x_i}}{\sum_{j=1}^{n} e^{x_j}}$$

$$\boxed{e^{x_i} / \sum_{j=0}^{n-1} e^{x_j}.}$$

- The softmax function is used as the activation function for multi-class classification problems where class membership is required on more than two class labels.

# How to Choose an Output Activation Function

- We choose the activation function for your output layer based on the prediction problem we are solving.
- If a problem is a regression problem, we should use a linear activation function.
- If a problem is a classification problem, then there are three main types of classification problems, and each may use a different activation function.
  1. Binary classification: One node, sigmoid activation.
  2. Multiclass classification: One node per class, softmax activation
  3. Multilabel classification: One node per class, sigmoid activation

Note: Multiclass classification makes the assumption that each sample is assigned to one and only one label. Multilabel classification assigns to each sample a set of target labels.

# When to Use Multi-layer Perceptrons?

- Multi-layer perceptrons are suitable for classification prediction problems where inputs are assigned a class or label.
- They are also suitable for regression prediction problems where a real-valued quantity is predicted given a set of inputs. Data is often provided in a tabular format, such as we would see in a CSV file or a spreadsheet.

# That's all!

# Any questions?
